Nikola Janjušević, February 12, 2023

Problem 1 (Presentation). On "KAISA: An Adaptive Second-Order Optimizer Framework for Deep Neural Networks". See JANJUSEVIC_NIKOLA.pdf for slides.

Problem 2 (Matrix-matrix multiplication (MMM)).

We edit and compile MMutlo.cpp, a program that does matrix-matrix multiplication naively via a tripple nested for loop. For multiplication matrices $C \leftarrow C + AB$ of shapes $C \in \mathbb{R}^{m \times n}$, $A \in \mathbb{R}^{m \times k}$, and $B \in \mathbb{R}^{k \times n}$, the inner iteration at indices (i, j, p) of the loop consists of:

- 1) reading A_{ip} , B_{pj} , and C_{ij} (i.e. 3 reads)
- 2) C_ij += A_ip * B_pj (i.e. 1 add and 1 multiply)
- 3) writing to C_{ij}

Hence, our total number of flops per MMM is 2mnk, and our total memory read/write per MMM is 4mnk * sizeof(double) = 64mnk. Note that this is not an optimal implementation of MMM, nor an optimal implementation of naive MMM.

The following tests were run on an Intel Core i5-8250U CPU, a 64 bit x86 processor with a max clock frequency of 3.4 GHz and a maximum bandwidth of 35.76 GB/s. The processor has an L1, L2, and L3 cache size of 256 kB, 1 MB, and 6 MB, respectively¹. The code with compiled with g++ 12.2.0.

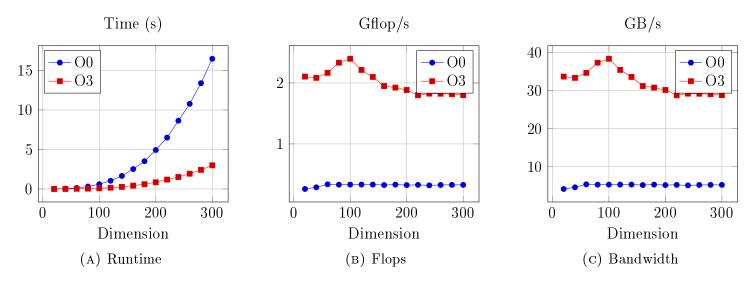

FIGURE 1. MMult0.cpp output over different compliation optimization levels (O0, O3). Plotting code (pgfplots) generated by ChatGPT.

Figure 1 shows the output of the matrix multiplication program under different optimization levels. In this setting M=N=K=dimension. We see that without optimization, the code

¹https://en.wikichip.org/wiki/intel/core_i5/i5-8250u

stagnates its performance in terms of flops and bandwidth. With optimization, the runtime increases while flops and bandwidth decrease with optimization level dimension. The use of compiler optimization also brings the performance of the program close to the manufacturer's specifications for the processor.

An interesting note is the relative plateu of performance in the dimension=[10,100] range. This can be explained by the size of the L1 cache being 256 kB, which can hold 3 $N \times N$ matrices of (roughly up) to size N = 103. After dimension 100, slower forms of memory are likely being used and we observe a sharp decrease in performance.

Problem 3 (Laplace 1D).

laplace.cpp (given at the end of this document) implements Jacobi and Gauss-Seidel solvers for the 1D Laplace equation with Dirichlet boundary conditions. The program was compared against the analytical solution $u(x) = \frac{1}{2}x(1-x), x \in [0,1]$ for correctness. Table 1 shows the statistics of the algorithms when compiled and run on the processor described in the previous problem.

TABLE 1. laplace.cpp solver stats over dimension (N) and compiler optimization (O0, O3), maxit=50000.

Solver	Stats	Dimension (N)			
		10	100	1k	$100 \mathrm{k}$
Jacobi	O0-time	2e-4	0.080	1.85	156
	O3-time	2e-5	4e-3	0.095	11.4
	iters	222	18830	50k	50k
	$\operatorname{residual}$	3e-4	1e-2	22.29	315.4
Gauss-Seidel	O0-time	6e-4	0.035	1.79	145
	O3-time	8e-6	3e-3	0.18	17.9
	iters	112	9416	50k	50k
	$\operatorname{residual}$	3e-4	1e-2	22.29	315.4

After N=1,000, neither solver is able to run to convergence. We observe that the Gauss-Seidel algorithm is per-iteration slower than Jacobi but has a faster runtime when given enough time to converge (as it uses less iterations). Enabling compilation optimization speeds up both algorithms by an order of magnitude.

MMult0.cpp

```
1 // + Experiment with different optimization levels from -00 to -03 and
        the flop-rate and the bandwidth observed on your machine.
3 // + Specify the the compiler version (using the command: "g++ -v")
4 // + Try to find out the frequency, the maximum flop-rate and the maximum
      main
5 //
       memory bandwidth for your processor.
